## About the Authors

**Jerome Henry, CCIE No. 24750**, is a Distinguished Engineer in the Office of the Wireless CTO at Cisco Systems. Jerome has more than 20 years' experience teaching technical Cisco courses, in more than 15 countries and four languages, to audiences ranging from bachelor's degree students to networking professionals and Cisco internal system engineers. Focusing on his wireless and networking experience, Jerome joined Cisco in 2012. Before that time, he was consulting and teaching about heterogeneous networks and wireless integration with the European Airespace team, which was later acquired by Cisco to become its main wireless solution. He then spent several years with a Cisco Learning Partner, developing networking courses and working on training materials for emerging technologies.

Jerome is a certified wireless networking expert (CWNE No. 45), has developed multiple Cisco courses, and has authored several books and video courses on wireless technology. Jerome holds more than 500 patents, is a member of the IEEE, where he was elevated to Senior Member in 2013, and also represents Cisco in multiple Wi-Fi Alliance working groups. With more than 10,000 hours in the classroom, Jerome was awarded the IT Training Award Best Instructor silver medal. He is based in Research Triangle Park, North Carolina.

**David Hucaby, CCIE No. 4594, CWNE No. 292**, is a technical education content engineer for Cisco Meraki. Previously, he worked as a wireless escalation engineer in a large healthcare environment for over 20 years. David holds bachelor's and master's degrees in electrical engineering. He has been authoring Cisco Press titles for 25 years. David lives in Kentucky.

## About the Technical Reviewer

**Samuel Clements, CCIE Wireless No. 40629**, is a Mobility Technical Solutions Architect for World Wide Technology (wwt.com), a Global VAR. He is CWNE No. 101 and is active in all things Wi-Fi. You can find him blogging at <http://www.sc-wifi.com/> and on X (formerly Twitter) at @samuel\_clements. When he's not doing Wi-Fi things, he's spending time in Tennessee with his wife of 15 years, Sara, and his two children, Tristan and Ginny.

## Dedications

In many ways, this century (and probably the previous ones) resembles Wi-Fi. Every few years, new developments fundamentally change the way we work and communicate. Each time we look back a few years, we realize that today we have more information to absorb and more new technologies to understand. What was concluded as impossible is now experimented with or achieved sooner and faster than we thought. As you open this book, dear reader, to prepare for the CCNP exam, this step may look steep today, but it will soon be just a memory of a time you knew less and could do less. Your will to excel and deepen your knowledge is what you, dear reader, give to us, the authors, as a reason to continue sharpening our expertise and sharing what we have learned on the way. So this book is for you, dear reader, and your aspiration to excellence. As my family blazon says, *sic itur ad astro*: “this is how you reach for the stars.”

—*Jerome Henry*

As always, my work is dedicated to my wife, my daughters, and my twin grandsons, for their love and support, and to God, who has blessed me with opportunities to learn, write, and work with so many friends—abundant life indeed!

—*David Hucaby*

## Acknowledgments

My dear wife, Corinne, often says that she knows “that look,” she knows “that pace,” when I walk back and forth in the corridor of our home leading to my office. She knows when I am not satisfied with a sentence, critical of an explanation that I do not find clear enough, or unhappy with an example or an analogy that does not quite work like it should. Each time, she patiently throws me a question to help me verbalize the problem and, in the end, puts her finger on what was missing. This book would not have been possible without her patience. “Patience made human” is also how I see Brett Bartow and Nancy Davis, who helped us navigate the complexity of changing exam scopes, and Ellie Bru, who week after week herded us, her authors, corrected our mistakes, and patted our backs to help us stay at the level of quality she expected. If this book is not a collection of disorganized notes on pieces of napkins, it is thanks to them. And, of course, flying with multiple pilots only works if each of them mixes excellence in their domain, acceptance that another one may be covering the left or the right field, and a permanent re-assessment of who is where, who has covered what, and who has left what gap or ground to complete. I could not dream of a better co-pilot than Dave, who was kind enough to accept me and enjoy this flight together.

—*Jerome Henry*

It’s again a great pleasure to have worked on a project with Jerome Henry, whom I have long admired for his Wi-Fi knowledge and experience. He’s not only that—he’s been a superb co-author and a kind and gracious friend. Ellie Bru has been an awesome development editor and has kept us motivated all along the way with encouragement and funny GIFs. I’m grateful to Brett Bartow and Nancy Davis for giving me another opportunity to write. Many thanks to Samuel Clements for his fine technical editing, expertise, and review. I have graduated from reading his blog to reading his comments and suggestions.

## Command Syntax Conventions

The conventions used to present command syntax in this book are the same conventions used in the IOS Command Reference. The Command Reference describes these conventions as follows:

- **Boldface** indicates commands and keywords that are entered literally as shown. In actual configuration examples and output (not general command syntax), boldface indicates commands that are manually input by the user (such as a **show** command).
- *Italic* indicates arguments for which you supply actual values.
- Vertical bars (|) separate alternative, mutually exclusive elements.
- Square brackets ( [ ] ) indicate an optional element.
- Braces ( { } ) indicate a required choice.
- Braces within brackets ( [ { } ] ) indicate a required choice within an optional element.

## Introduction

Congratulations! If you are reading this Introduction, then you have probably decided to obtain a Cisco certification. Obtaining a Cisco certification will ensure that you have a solid understanding of common industry protocols along with Cisco's device architecture and configuration. Cisco has a high market share of network infrastructure of routers, switches, and firewalls, with a global footprint.

Professional certifications have been an important part of the computing industry for many years and will continue to become more important. Many reasons exist for these certifications, but the most popularly cited reason is credibility. All other factors being equal, a certified employee/consultant/job candidate is considered more valuable than one who is not certified.

Cisco provides three levels of certifications: Cisco Certified Network Associate (CCNA), Cisco Certified Network Professional (CCNP), and Cisco Certified Internetwork Expert (CCIE). Cisco made changes to all three certifications, effective February 2020. The following are the most notable of the many changes:

- The exams include additional topics, such as programming.
- The CCNA certification is not a prerequisite for obtaining the CCNP certification.
- CCNA specializations are no longer offered.
- The exams test a candidate's ability to configure and troubleshoot network devices in addition to their ability to answer multiple-choice questions.
- The CCNP is obtained by taking and passing a Core exam and a Concentration exam.
- The CCIE certification requires candidates to pass the Core written exam before the CCIE lab can be scheduled.

CCNP Enterprise candidates need to take and pass the Implementing and Operating Cisco Enterprise Network Core Technologies ENCOR 350-401 examination. Then they need to take and pass one of the following Concentration exams to obtain their CCNP Enterprise:

- 300-410 ENARSI: Implementing Cisco Enterprise Advanced Routing and Services (ENARSI)
- 300-415 ENSDWI: Implementing Cisco SD-WAN Solutions (ENSDWI)
- 300-420 ENSLD: Designing Cisco Enterprise Networks (ENSLD)
- 300-425 ENWLSLSD: Designing Cisco Enterprise Wireless Networks (ENWLSLSD)
- 300-430 ENWLSI: Implementing Cisco Enterprise Wireless Networks (ENWLSI)
- 300-435 ENAUTO: Automating and Programming Cisco Enterprise Solutions (ENAUTO)

This book helps you study for the CCNP ENWLSLSD 300-425 and ENWLSI 300-430 exams. The time allowed to take each test is 90 minutes to complete about 60 questions. Testing is done at Pearson VUE testing centers.

Be sure to visit [www.cisco.com](http://www.cisco.com) to find the latest information on CCNP Concentration requirements and to keep up to date on any new Concentration exams that are announced.

## Goals and Methods

The most important and somewhat obvious goal of this book is to help you pass the Designing Cisco Enterprise Wireless Networks ENWLSLSD 300-425 and Implementing Cisco Enterprise Wireless Networks ENWLSI 300-430 exams. In fact, if the primary objective of this book were different, the book's title would be misleading; however, the methods used in this book to help you pass the ENWLSLSD 300-425 and ENWLSI 300-430 exams are designed to also make you much more knowledgeable about how to do your job. While this book and the companion website together have more than enough questions to help you prepare for the actual exam, the goal is not to simply have you memorize as many questions and answers as you possibly can.

One key methodology used in this book is to help you discover the exam topics you need to review in more depth, to help you fully understand and remember those details, and to help you prove to yourself that you have retained your knowledge of those topics. So, this book does not try to help you pass by memorization; rather, it helps you truly learn and understand the topics. Designing and implementing enterprise wireless networks are two of the concentration areas you can focus on to obtain the CCNP certification, and the knowledge contained within this book is vitally important to consider yourself a truly skilled enterprise wireless networks engineer. This book will help you pass the ENWLSLSD 300-425 and ENWLSI 300-430 exams by using the following methods:

- Helping you discover which test topics you have not mastered
- Providing explanations and information to fill in your knowledge gaps
- Supplying exercises and scenarios that enhance your ability to recall and deduce the answers to test questions

## Who Should Read This Book?

This book is not designed to be a general wireless networking topics book, although it can be used in that way. This book is intended to tremendously increase your chances of passing the Designing Cisco Enterprise Wireless Networks ENWLSLSD 300-425 and Implementing Cisco Enterprise Wireless Networks ENWLSI 300-430 CCNP specialization exams. Although other objectives can be achieved from using this book, the book is written with one goal in mind: to help you pass the exams.

## Strategies for Exam Preparation

The strategy you use to study for the ENWLSD or ENWLSI exam might be slightly different than strategies used by other readers, mainly depending on the skills, knowledge, and experience you have already obtained. For instance, if you have attended the ENWLSD or ENWLSI course, then you might take a different approach than someone who has learned based on job experience alone.

Regardless of the strategy you use or the background you have, the book is designed to help you get to the point where you can pass the exam in the least amount of time. For instance, there is no need for you to practice or read about IP addressing and subnetting if you fully understand it already. However, many people like to make sure they truly know a topic and thus read over material they already know. Several book features will help you gain the confidence you need to be convinced that you know some material already and to also help you know what topics you need to study more.

Each version of the exam may include topics that emphasize different functions or features, and some topics can be rather broad and generalized. The goal of this book is to provide comprehensive coverage to ensure that you are well prepared for the exam. Although some chapters might not address specific exam topics, they provide a foundation that is necessary for a clear understanding of important topics. Your short-term goal might be to pass an exam, but your long-term goal should be to become a qualified CCNP Enterprise wireless engineer.

It is also important to understand that this book is a static reference, whereas the exam topics are dynamic. Cisco can and does change the topics covered on certification exams often.

This exam guide should not be your only reference when preparing for the certification exam. You can find a wealth of information available at Cisco.com that covers each topic in great detail. If you think you need more detailed information on a specific topic, read the Cisco documentation that focuses on that topic.

Note that as CCNP Enterprise wireless network technologies continue to evolve, Cisco reserves the right to change the exam topics without notice. Although you can refer to the list of exam topics in Table I-1, always check Cisco.com to verify the actual list of topics to ensure that you are prepared before taking the exam. You can view the current exam topics on any current Cisco certification exam by visiting the Cisco.com website, choosing Menu, clicking Training & Events, and then selecting from the Certifications list. Note that, if needed, Cisco Press might post additional preparatory content on the web page associated with this book, at [www.ciscopress.com/title/9780138249892](http://www.ciscopress.com/title/9780138249892). It's a good idea to check the website a couple of weeks before taking your exam to be sure that you have up-to-date content.

## How to Access the Pearson Test Prep (PTP) App

You have two options for installing and using the Pearson Test Prep application: a web app and a desktop app. To use the Pearson Test Prep application, start by finding the registration code that comes with the book. You can find the code in these ways:

- You can get your access code by registering the print ISBN (9780138249892) on [ciscopress.com/register](http://ciscopress.com/register). Make sure to use the print book ISBN, regardless of whether you purchased an eBook or the print book. After you register the book, your access code will be populated on your account page under the Registered Products tab. Instructions for how to redeem the code are available on the book's companion website by clicking the Access Bonus Content link.
- If you purchase the Premium Edition eBook and Practice Test directly from the Cisco Press website, the code will be populated on your account page after purchase. Just log in at [ciscopress.com](http://ciscopress.com), click Account to see details of your account, and click the digital purchases tab.

Once you have the access code, to find instructions about both the PTP web app and the desktop app, follow these steps:

**NOTE** After you register your book, your code can always be found in your account under the Registered Products tab.

- Step 1.** Open this book's companion website, as shown earlier in this Introduction, under the heading, "How to Access the Companion Website."
- Step 2.** Click the **Practice Exams** button.
- Step 3.** Follow the instructions listed there for both installing the desktop app and using the web app.

Note that if you want to use the web app only at this point, just navigate to [pearsonstestprep.com](http://pearsonstestprep.com), log in using the same credentials used to register your book or purchase the Premium Edition, and register this book's practice tests using the registration code you just found. The process should take only a couple of minutes.

## Customizing Your Exams

Once you are in the exam settings screen, you can choose to take exams in one of three modes:

- **Study mode:** Allows you to fully customize your exams and review answers as you are taking the exam. This is typically the mode you would use first to assess your knowledge and identify information gaps.
- **Practice Exam mode:** Locks certain customization options, as it is presenting a realistic exam experience. Use this mode when you are preparing to test your exam readiness.
- **Flash Card mode:** Strips out the answers and presents you with only the question stem. This mode is great for late-stage preparation when you really want to challenge yourself to provide answers without the benefit of seeing multiple-choice options. This mode does not provide the detailed score reports that the other two modes do, so you should not use it if you are trying to identify knowledge gaps.

In addition to these three modes, you will be able to select the source of your questions. You can choose to take exams that cover all of the chapters, or you can narrow your selection to just a single chapter or the chapters that make up specific parts in the book. All chapters are selected by default. If you want to narrow your focus to individual chapters, simply deselect all the chapters and then select only those on which you wish to focus in the Objectives area.

You can also select the exam banks on which to focus. Each exam bank comes complete with a full exam of questions that cover topics in every chapter. You can have the test engine serve up exams from all test banks or just from one individual bank by selecting the desired banks in the exam bank area.

There are several other customizations you can make to your exam from the exam settings screen, such as the time of the exam, the number of questions served up, whether to randomize questions and answers, whether to show the number of correct answers for multiple-answer questions, and whether to serve up only specific types of questions. You can also create custom test banks by selecting only questions that you have marked or questions on which you have added notes.

## Updating Your Exams

If you are using the online version of the Pearson Test Prep practice test software, you should always have access to the latest version of the software as well as the exam data. If you are using the Windows desktop version, every time you launch the software while connected to the Internet, it checks whether there are any updates to your exam data and

automatically downloads any changes that were made since the last time you used the software.

Sometimes, due to many factors, the exam data may not fully download when you activate your exam. If you find that figures or exhibits are missing, you may need to manually update your exams. To update a particular exam you have already activated and downloaded, simply click the **Tools** tab and click the **Update Products** button. Again, this is an issue only with the desktop Windows application.

If you wish to check for updates to the Pearson Test Prep exam engine software, Windows desktop version, simply click the **Tools** tab and click the **Update Application** button. This ensures that you are running the latest version of the software engine.

## CHAPTER 4

# Physical and Logical Infrastructure Requirements

### This chapter discusses the following topics:

**Physical Infrastructure Requirements:** Powering an access point with Power over Ethernet (PoE) has several variants, including delivering power directly from a switch or through a *power injector*. However, PoE itself comes in several flavors that have cabling infrastructure dependencies. This section discusses the main types of PoE, including *PoE*, *PoE+*, *UPoE*, and *UPoE+*, and the types of cables that support them. In addition, as modern 802.11 standards begin to push beyond 1Gbps, traditional Ethernet connections over twisted pair cable are no longer enough to support the maximum performance capabilities of the access point. This section discusses the improved performance characteristics of mGig and the network requirements necessary. This section also discusses AP mounting and grounding strategies.

**Logical Infrastructure Requirements:** This section discusses the logical elements of a wireless network, such as the communication flow of the CAPWAP control and data channels as they traverse the network, and their implications on the underlying physical infrastructure. In addition, this section discusses controller and AP licensing mechanisms.

### This chapter covers the following ENWLS D exam topics:

- 2.1 Determine physical infrastructure requirements such as AP power, cabling, switch port capacity, mounting, and grounding
- 2.2 Determine logical infrastructure requirements such as WLC/AP licensing requirements based on the type of wireless architecture

The focus of wireless network design often revolves around the RF aspects of the deployment—and indeed, as discussed throughout this book, RF design is the foundation of any successful wireless network and almost always involves a robust site survey. However, there are key infrastructure components that are just as important in any wireless design exercise. These are generally grouped into two major classes: the physical infrastructure components and logical infrastructure components.

The physical infrastructure includes components of the physical networking gear. This involves the physical gear itself, as well as how the access points are cabled, powered, mounted, and even grounded. This design aspect goes far beyond just the access points and the controller. For example, if a switch is used to deliver PoE to an AP, the switch must be able to accommodate the power requirements of the AP. If it cannot, either the AP will not power on or certain capabilities (such as secondary radios) will not work.

Additionally, the reachability of the APs over standard Ethernet cabling becomes a design criterion as distances from the switch grow and as higher data rates are used. When the

existing cable plant cannot support the distances demanded by the placement of APs, suboptimal AP placement may be used, which in turn may lead to poor RF coverage. Understanding the design requirements of the physical infrastructure is a crucial aspect of developing a successful wireless design.

The second infrastructure aspect is the logical network—in other words, the path the communication flows take through the network, regardless of the underlying physical infrastructure. Controller-based wireless networks use CAPWAP (Control And Provisioning of Wireless Access Points), both as a control channel as well as to encapsulate client data traffic, effectively tunneling client traffic directly from the AP to the controller, and vice versa. This gives the logical appearance that the APs and controller are Layer 2 adjacent, when in reality they may be traversing many hops of the underlying physical network. Understanding the behavior and function of these logical elements introduces important considerations when developing the infrastructure side of the wireless design.

This chapter focuses on these two infrastructure aspects, beginning with the physical infrastructure and followed by the logical infrastructure.

## Foundation Topics

### Physical Infrastructure Requirements

The physical infrastructure of a wireless network includes all physical elements, including the access points, controllers, switches and routers, and any other physical network devices that facilitate communication between the wireless users and the network they are trying to access. In addition to networking devices, the physical infrastructure includes power delivery, cabling, mounting, and grounding of access points.

## PoE and PoE+

Power over Ethernet (PoE) is a widely used infrastructure technology that allows DC power to be provided to an endpoint over a twisted pair Ethernet cable. Power is passed from *power sourcing equipment (PSE)*, such as a PoE-capable switch, over the existing twisted pair Ethernet cable that carries data communications to *powered devices (PDs)*, such as IP phones, video cameras, wireless access points, point-of-sale machines, access control card readers, LED luminaires, and many more. Through the use of PoE, external powering of endpoints is not required, thus greatly reducing the cost and effort required to deploy electrical power throughout the infrastructure. Typically, for a company to deploy electrical cabling in the ceiling requires a certified electrician to perform the task, whereas the deployment of Ethernet cables (which can run PoE) can be done by anyone, thus greatly simplifying the job of deploying access points wherever they need to go.

The power requirements of endpoints vary based on their power consumption requirements, which is typically a function of the physical function, application, and complexity of the device. For example, basic IP phones might draw approximately 6W of power, whereas contemporary LED lighting fixtures can draw up to 50W for routine operation. Wireless APs draw different power levels depending on which features are enabled and how many radios are concurrently active. For example, the Cisco Catalyst 9100 AP typically draws slightly more than 30W with all features turned on.

Power delivery over Ethernet twisted pair is based on the IEEE 802.3af (2003) standard and delivers up to 15.4W of DC power per port of the PSE; however, due to power dissipation in the cable, only 12.95W of this is available to the PD.

After the initial introduction of PoE in 2003, endpoints were soon demanding greater power than 802.3af could deliver. Thus, in 2009, IEEE 802.3at was standardized, known as PoE Plus (PoE+). PoE+ delivers up to 30W of DC power per port, ensuring 25.5W of power to a PD due to power dissipation.

In both of these cases, PoE delivers power over two of the four twisted pairs of Class D/Category 5e or better cabling. The PSE uses only signal pairs—that is, the pairs formed by pins 1 and 2 and pins 3 and 6—to transport power from the PSE to the PD and leaves the spare pairs idle (consisting of pins 4 and 5 and pins 7 and 8). Note that PoE does not affect the network performance of Ethernet links to the PD.

## UPOE and UPOE+

In recent years the enterprise workspace has continued to evolve, resulting in increasing numbers of devices and workloads converging onto the IP network. This has fueled increasing demand for higher PD power draw, far in excess of what PoE and PoE+ can offer (more than 25.5W).

To meet this demand, Cisco has developed extended PoE capabilities, including Universal PoE (UPOE), capable of delivering 60W per port, and Universal PoE Plus (UPOE+), which is capable of delivering up to 90W per port. Note that while PoE and PoE+ have been standardized by the IEEE, UPOE and UPOE+ are Cisco proprietary. In 2018, the IEEE defined 802.3bt as a standard to deliver up to 90W (sometimes referred to as PoE++).

The network's ability to deliver higher levels of power to endpoints has, in turn, significantly expanded the PoE-capable endpoint landscape. Thanks to these higher PoE capabilities, a wide variety of devices with higher power requirements can now be powered over Ethernet

without requiring separate electrical wiring. These include video endpoints, LED lighting fixtures, digital signage, compact switches, and, of course, larger and more robust access points.

802.3bt, UPOE, and UPOE+ all use the same cabling standard as PoE/PoE+; however, instead of delivering power over just two of the twisted pairs, these higher power embodiments of PoE utilize all four twisted pairs of standard Ethernet cabling (Category 5e or better). They do this by using two PSE controllers to power both the signal pairs and the spare pairs. Figure 4-1 presents the difference between PoE/PoE+ and Cisco UPOE/UPOE+.

**Figure 4-1** Comparing PoE/PoE+ with UPOE/UPOE+

In the case of PoE, PoE+, or UPOE, the minimum Ethernet cable type is Category 5e. In the case of UPOE+, Category 6a is required at a minimum. Regardless of the method of power over Ethernet, the maximum cable distance remains the same at 100 meters.

It is also important to note that support for the type of PoE desired depends on the capabilities of the Ethernet switch. For example, older switches may only support PoE/PoE+; however, modern switches (such as the Catalyst 9300) support UPOE, and certain higher-end switches (such as the Catalyst 9400) support UPOE+.

## Power Injectors

PoE delivered by an access switch is a natural choice to power APs in most wireless deployments. This greatly reduces the wiring required and allows flexible AP placement throughout a building. That being said, there are still use cases where PoE delivered by the access switch is not practical, and power injectors must be considered. For example, there may be places where the switch simply doesn't support the necessary PoE mode, or perhaps the switch has no available PoE-capable ports, or it may even have a severely limited power budget due to too many other PDs. In some cases, certain APs with full features enabled may have greater power demands than a legacy PoE switch can offer. In these situations, using a power injector is a simple and often appealing alternative.

Power injectors generally have two Ethernet inputs: one connected to the upstream switch and another connected to the PD (that is, the access point). The power injector is also plugged into a power source via the 48V DC power supply, which then injects power into the two pairs, supporting PoE and PoE+.

Cisco power injectors are offered in two form factors. The first variant supports copper Category 5e or better cables both on the input and output (connected to the switch and to the access point). In this case, maximum cable distance from switch to AP remains at 100 meters—that is, the power injector does not function as a repeater and increase the maximum transmission distance over the twisted pair cable.

The second variant is a fiber optic link between the switch and the power injector. In this case, the power injector functions as a media converter and injects power onto the twisted pair cable that connects to the access point. Using single-mode fiber allows the power injector to be placed up to 2 kilometers from the switch, making it a practical option for places where the AP is far away, such as large factories, warehouses, and other places with sparse wiring closets.

Figure 4-2 illustrates the two power injector options for Cisco access points.

## MultiGigabit

With increasing performance speeds of 802.11ac Wave 2 (Wi-Fi 5) and more recently 802.11ax (Wi-Fi 6), the maximum theoretical wireless throughput of an access point is pushing well beyond the 1Gbps capability of traditional Ethernet access, potentially making the single wired uplink between the AP and switch a chokepoint.

To solve this problem, Cisco has championed the development of MultiGigabit (mGig) technology that delivers speeds of 2.5Gbps, 5Gbps, or 10Gbps on existing cables. The NBASE-T Alliance (created in 2014) initially led the standards development of MultiGigabit over Ethernet, but it was eventually merged with the Ethernet Alliance in April 2019 and is now marketed as mGig by Cisco. In addition to traditional Ethernet speeds over Category 5e cable, Cisco mGig supports speeds of 2.5Gbps, 5Gbps, and 10Gbps. The technology also supports PoE, PoE+, and Cisco UPOE.

The main characteristics mGig are as follows:

- **Variable speeds:** Cisco mGig technology supports auto-negotiation of multiple speeds on switch ports (100Mbps, 1Gbps, 2.5Gbps, and 5Gbps on Cat 5e cable, and up to 10Gbps over Cat 6a cabling).
- **Flexible cable types:** mGig supports a wide range of cable types, including Cat 5e, Cat 6, and Cat 6a or above.
- **PoE power:** The technology supports PoE, PoE+, and UPOE (up to 60W) for all the supported speeds and cable types, providing access points with additional power for advanced features, such as hyperlocation and modularity.

Figure 4-3 illustrates the use of mGig between a capable access switch and an access point.

**Figure 4-3** MultiGigabit Connection to an Access Point

Cisco 3800 and 4800 series access points (802.11ac Wave 2) and Cisco Catalyst 9100 series APs (Wi-Fi 6/6E, 802.11ax) support Cisco mGig technology at speeds of 2.5Gbps and 5Gbps. This technology protects the investment in the cabling infrastructure, allowing for newer and faster wireless technologies to be transported over the same physical Ethernet infrastructure without becoming a chokepoint.

To summarize, Table 4-3 illustrates the different mGig speeds and supported cable categories.

## Mounting Access Points

Wireless deployments often require a variety of different AP mounting options depending on the physical attributes and accessibility of each location. To address this, Cisco offers

several different mounting bracket options. In addition, several third-party vendors provide mounting brackets and enclosures for less common scenarios.

This section discusses the three most common options for mounting Cisco APs:

- Ceiling and wall mounting
- Mounting below ceiling tiles
- Mounting above ceiling tiles

### Ceiling and Wall Mounting Access Points

When mounting on a horizontal or vertical surface, you can use one of the two standard mounting brackets:

- **AIR-AP-BRACKET-1:** This mounting option features a low profile, making it a popular choice for ceilings.
- **AIR-AP-BRACKET-2:** This is a universal mounting bracket that is often used if the AP will be mounted on the wall or placed in a NEMA (National Electrical Manufacturers Association) enclosure.

Figure 4-4 illustrates the two mounting bracket options.

AIR-AP-BRACKET-1 (low profile)

AIR-AP-BRACKET-2 (universal)

**Figure 4-4** Cisco Access Point Mounting Bracket Options

When wall mounting is desired, the installer should understand that walls can be a physical obstacle to the RF signal; therefore, maintaining 360-degree coverage can be compromised by the wall if the AP is not placed correctly. If the wall is an outside wall and/or if the goal is to transmit the signal in a narrower beam (such as down a food aisle in a grocery store), a directional antenna may be a better choice, assuming the external antenna model of an AP is used.

In most cases, it is recommended to avoid wall-mounting APs with internal antennas, as the antenna orientation of these APs is optimally designed for ceiling mount, providing RF coverage in a 360-degree pattern to the space below the floor. If the AP is wall mounted, it is recommended to use either a right-angle mount (where the AP is still oriented downward) or external antennas that project the RF energy into the space as expected. For this reason, it is generally recommended to mount indoor APs on the ceiling rather than on a wall.

## Mounting Access Points Below a Suspended Ceiling

To facilitate mounting APs below a suspended ceiling, specialized mounting brackets are available that clip onto the rail of a T-bar ceiling. Figures 4-5 and 4-6 illustrate the mounting bracket for these types of ceilings.

**Figure 4-5** T-Bar Ceiling Mounting Bracket Options

**Figure 4-6** T-Bar Ceiling Mounting Bracket Detail

## Mounting Access Points Above the Ceiling Tiles

Mounting access points below the ceiling tiles is the preferred option; however, in some cases, wireless engineers may prefer to position the access points so that nothing is visible from the ground, or there may be a building facilities policy that prohibits any device from attaching to the suspended ceiling. Mounting above the ceiling tiles may also be preferred for aesthetic reasons, or it may be done as a way to reduce theft in vulnerable areas (such as public hotspots where theft or damage may be a problem). In such circumstances, Cisco indoor access points, such as the Catalyst 9100 series, have a UL-2043 rating for installation in the plenum area above the suspended ceiling, allowing them to be attached to the T-bar mesh but suspended above the tile.

Figure 4-7 illustrates a mounting schematic for an AP above the ceiling tiles.

2	Box hanger	5	Access point
3	Box hanger clip	6	T-rail clip

**Figure 4-7** *Mounting the Access Point Above the Ceiling Tiles*

When mounting the AP above the ceiling tiles, it is important to remember that the tiles must not be conductive, as this would have a degrading effect on the RF performance of the AP and may interfere with wireless LAN features that depend on uniform coverage, such as voice and location services. Additionally, the AP should be mounted as close to the center of the ceiling tile as possible and away from any possible obstructions, such as metal ducts, pipes, cabling, or other metal objects that could interfere with RF performance.

### Grounding and Securing Access Points

Grounding is not always required for indoor installations because access points are classified as low-voltage devices and do not contain internal power supplies. However, electrical grounding is always recommended for outdoor access points. It is always best to check with local electrical standards to determine if grounding is necessary.

Although grounding is not mandatory for most indoor access points, it is required in certain scenarios. For example, in underground scenarios such as mining operations, indoor access points that are mounted too close to an electromagnetic source of interference, such as a fluorescent light, may reboot suddenly or suffer hardware damage. This may occur even if the AP is not physically touching the electrical source but is just in close proximity to the electromagnetic source of interference. Grounding the access point or the mounting bracket helps prevent this issue from occurring. A certified electrical technician should verify whether the installation requires grounding.

Figure 4-8 shows an outdoor access point with the grounding connector.

## Logical Infrastructure Requirements

The path that traffic flow takes through a network can appear differently depending on your point of view. For example, from a network technician's point of view, a packet travels through the network in a hop-by-hop path across each physically connected device. However, from a wireless end user's perspective, if traffic is tunneled in a CAPWAP overlay, the user may only see one hop between an access point and the controller, when in reality numerous physical hops were encountered along the path of the underlying network. This is the difference between the physical and logical network.

Traffic also flows differently depending on the deployment model chosen: autonomous access points act as direct links between the wireless and the wired sides of the network, whereas centrally controlled access points in Local mode must forward all wireless client traffic to the controller over an encapsulated CAPWAP tunnel. In FlexConnect mode, some WLANs may be locally switched at the AP, while others may be centrally switched on the controller.

The following section will explore some of the logical infrastructure characteristics of a wireless network, including flow of the CAPWAP channels, logical connections to services supporting the wireless infrastructure such as AAA and DHCP servers, and finally the licensing options that are available to support the wireless deployment.

### CAPWAP Flow

CAPWAP is a logical network connection protocol between access points and a wireless LAN controller. CAPWAP is used to manage the behavior of the APs as well as tunnel encapsulated 802.11 traffic between the AP and the controller.

CAPWAP sessions are established between the AP's logical IP address (obtained through DHCP) and the controller's **management interface**. Controllers based on IOS XE have a single IP address that is used for all purposes. In older versions of AireOS, the CAPWAP session terminated on the **ap-manager** interface; however, this has been changed to the management interface in more recent versions of AireOS.

Whether in Local or FlexConnect mode, CAPWAP sessions between the controller and AP are used to manage the behavior of the AP. When in Local mode, CAPWAP is additionally

used to encapsulate and tunnel all wireless client traffic so that it can be centrally processed by the controller. CAPWAP sessions use UDP for both the control and data channels, as follows:

- **CAPWAP Control Channel:** Uses UDP port 5246
- **CAPWAP Data Channel:** Uses UDP port 5247 and encapsulates (tunnels) the client's 802.11 frames
- Figure 4-9 illustrates the different CAPWAP channels between an AP and a controller.

**Key  
Topic**

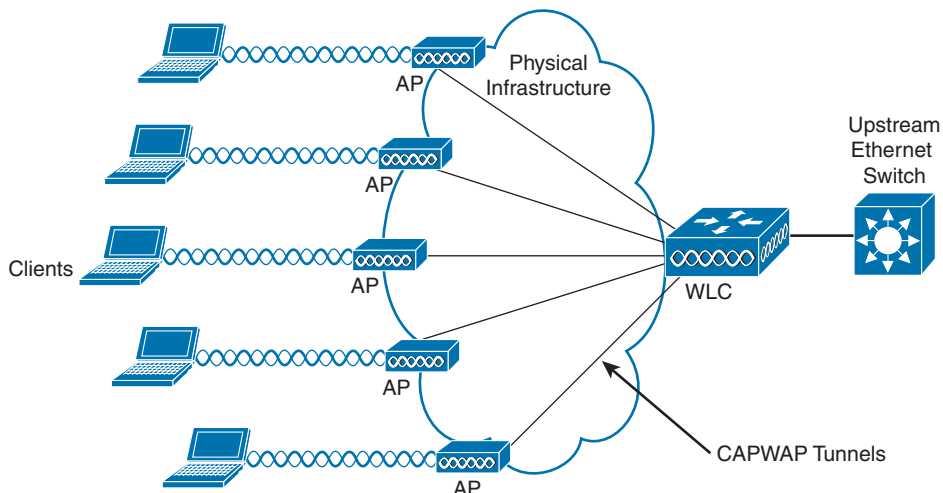

**Figure 4-9** CAPWAP Control and Data Plane Channels

If there is a firewall or router with access control lists (ACLs) along the logical path between the AP and the controller, it is important to ensure that rules are in place to allow both the CAPWAP control and data channel ports through the firewall so that the AP and controller are able to communicate correctly. A complete list of recommended firewall rules can be found here:

<https://www.cisco.com/c/en/us/support/docs/wireless/5500-series-wireless-controllers/113344-cuwn-ppm.html>

As the number of APs grows, so does the number of CAPWAP tunnels terminating on the controller. Figure 4-10 illustrates the logical connection of multiple CAPWAP sessions over the physical infrastructure.

**Figure 4-10** CAPWAP Sessions Between the APs and the Controller

**NOTE** In Autonomous mode, the AP switches all traffic locally and CAPWAP is not used. In FlexConnect mode, wireless client traffic is switched locally while control of the AP is managed over the CAPWAP control channel. Only centrally controlled APs in Local mode use both the CAPWAP control and data channels. FlexConnect mode may use a hybrid—some WLANs may be locally switched while others are centrally switched, where the data traffic comes back to the controller over the CAPWAP data channel. In either case, FlexConnect APs are still managed by the CAPWAP control channel.

Considering that all APs in Local mode use CAPWAP to tunnel 802.11 client traffic back and forth between the AP and the controller, an important design criterion related to traffic load must be considered. With 802.11ac Wave 2, the maximum theoretical throughput of a single AP is ~1.3Gbps. 802.11ax (Wi-Fi 6/6E) offers even greater speeds, with the theoretical throughput in excess of 10Gbps from a single AP (based on multiple streams). Considering the CAPWAP data channel will need to support increasing levels of data throughput (not to mention framing and packet overhead), the demands of the logical infrastructure have a direct correlation to capabilities of the underlying physical infrastructure. In this vein, careful analysis must be taken at various places in the network to determine if the performance demands of the wireless network can be met. This includes the following design aspects:

- The physical connection between the AP and the access switch (evaluate if mGig is required)
- An estimation of oversubscription of the uplink of the access switch to the network
- Backbone capacity of the core network
- WAN connection speeds if the controllers are centralized and APs are in Local mode
- Network access speeds to the controller
- Performance capabilities of the controller

From a design perspective, the theoretical maximum bandwidth consumption of an AP is usually never attained. However, if enough APs are simultaneously generating a high volume of traffic, a controller can quickly run out of resources. Take the example of a controller that is licensed for 500 APs. If these were all Wi-Fi 6/6E APs passing an excessively high volume of traffic, the aggregate bandwidth capacity of the physical connection to the controller could be quickly exhausted, meaning more controllers with fewer APs may be necessary.

Performance issues at the controller may manifest in two possible ways: (1) the underlying network's ability to aggregate all CAPWAP data traffic and forward it without oversubscription of the physical links connected to the controller, and (2) the controller's own performance limitations in being able to process the volume of data it is receiving.

If either of these two cases emerges, certain design changes can be considered. One change is decentralizing and splitting the function of the controllers such that less data is being managed by a single controller. Another option is to simply reduce the number of APs that each controller manages. If decentralizing the controllers is preferred, the roaming path must also be considered. While roaming between APs connected to the same controller is simple and should be seamless, if clients roam to an AP connected to a different controller, the roaming path will involve intercontroller communication and greater network complexity.

Another area where oversubscription may be an issue is on the access switch where the APs are physically connected. Take the example of an access switch with several dozen APs connected with mGig, all running Wi-Fi 6/6E. If the clients associated to these APs are generating large amounts of aggregate data, the throughput demands could quickly exhaust even a 10Gbps uplink from the access switch. Thus, it is imperative to assess not only how many APs are being deployed (and how many of each type), but also careful calculation must be made to determine if the uplink capacity of the access switches can accommodate expected traffic demands, including how much oversubscription is acceptable. If it is found that the oversubscription rate is excessive, then either multiple uplinks will be needed (which requires port channeling) or a fewer number of APs should be deployed on each access switch.

**NOTE** Oversubscription of centrally controlled APs over the WAN can be addressed using FlexConnect mode, which is discussed in detail in Chapter 10, “Implementing FlexConnect.”

### AAA and DHCP Services Logical Path

Another area where the logical path requires careful consideration is the path between the controller and the key services, such as the AAA and DHCP servers. Services such as AAA (ISE), DHCP, DNS, MSE/CMX, DNA Spaces, and many more may be placed at locations throughout the network that have firewalls protecting them. Understanding the logical path between these services will often require opening of firewall rules for the service to interface with the controller.

As with CAPWAP, the controller’s **management interface** is used to communicate with AAA servers, as well as a host of other services, including location servers, directory servers, syslog servers, other controllers, and more.

For DHCP, controllers proxy communication to the DHCP sever on behalf of clients using the controller’s IP address in the VLAN associated to the WLAN of those clients.

Table 4-4 summarizes the ports that must be open to allow the controller to communicate with key services.

Topic**

### Licensing Overview

In addition to purchasing the controller itself, Cisco wireless deployments require licenses to activate the use of the access points. The following section provides a summary of how Cisco wireless controllers and APs are licensed.

Cisco wireless controllers support two types of licensing models: *Right to Use (RTU)* licensing and Smart Licensing.

## Right to Use Licensing

Right to Use (RTU) licensing is an honor-based licensing mechanism that allows AP licenses to be enabled on wireless controllers (such as the 8500 series controllers) with *end user license agreement (EULA)* acceptance. The RTU license scheme simplifies the addition, deletion, and transfer of AP licenses and does not require specialized license keys or product activation key (PAK) licenses.

With RTU licensing, there are three types of licenses:

- **Permanent licenses:** The AP count is programmed into nonvolatile memory at the time of manufacturing. These licenses are not transferable from one controller to another.
- **Adder access point count licenses:** These are additional licenses that can be activated through the acceptance of the agreement. These licenses are also transferable between controllers and types of controllers.
- **Evaluation licenses:** These are used for demo and/or trial periods and are valid for 90 days, and they default to the full capacity of the controller. The evaluation license activation is performed through the command-line interface (CLI).

## Smart Licensing

*Smart Licensing* is a cloud-based flexible licensing model that simplifies the way licenses are managed across an organization rather than on a per-controller basis. The intent of Smart Licensing is to make it easier to manage and deploy Cisco software licenses from a central repository without having to track how licenses are used on individual products. IOS XE-based controllers like the Catalyst 9800 have migrated to Smart Licensing. While no licenses are required to boot up the controller, in order to connect any access points, Cisco DNA licenses managed through Smart Licensing are required for each access point that connects to the controller. While a missing license will not prevent an AP from joining the controller and operating normally, the controller will log the license gap. AireOS controllers support Smart Licensing in addition to the RTU licensing model.

Instead of using product activation keys (PAKs) or RTU licensing, Smart Licenses establish a central pool of AP software licenses in a customer-defined Smart Account that can be used across the enterprise and across all controllers or APs. Smart Licensed products self-register upon configuration and activation with a single token, removing the need to register products individually with separate PAKs or to accept a license agreement. Thus, instead of licensing each individual controller for the number of APs that the administrator anticipates it to manage, the pool of licenses can be shared across all controllers in the enterprise and be used as needed. This approach has a distinct advantage over legacy licensing models by greatly simplifying and optimizing the use of licenses.

In the RTU model, one controller may be licensed for far more APs than it is currently managing, whereas another controller may not have enough licenses for what it needs. Smart Licensing eliminates the overhead and waste by simply putting all AP licenses in a central pool that can be managed and budgeted for as the need arises. As new APs are added or moved across the organization, the administrator no longer needs to determine the current license count on a per-controller basis—only the Smart Licensing pool of AP licenses needs to be monitored and maintained. This not only provides better utilization of licenses but also it makes it easier to procure and deploy licenses as the organization grows.

To use Smart Licensing, the following steps must be followed:

**Step 1.** Create a Smart Account:

- a. Create a Smart Account at the following link: <https://software.cisco.com/software/company/smartaccounts/home#accountcreation-account>.
- b. Go to Cisco Software Central at [software.cisco.com](https://software.cisco.com).
- c. An editable profile appears.
- d. An email is automatically sent to the customer Smart Account administrator.

**Step 2.** Register the Cisco controller using the Smart Account.

- a. For existing customers, deposit existing licenses, if any, into the Smart Account.
- b. For a new purchase, purchase a Cisco DNA license for access points connecting to the Cisco Catalyst controller.

**Step 3.** Configure the license level on the controller, as desired.
